

$$E_{iso} = \frac{4\pi D_l^2}{(1+z)} \int_{1/1+z}^{10^4/1+z} EN(E)dE$$

$$E_{p,i} = E_{p,o}(1+z)$$

Interpretations:

Meszaros & Zhang
2002, Thompson
2007

$$E_p \propto R_0^{-1/2} t_j^{-1/4} E_{iso}^{1/2}$$

Rees & Meszaros
2005

$$E_{pk} \propto \Gamma^{-2} t_{var}^{-1} L^{1/2}$$

It allow to standardize this sources!

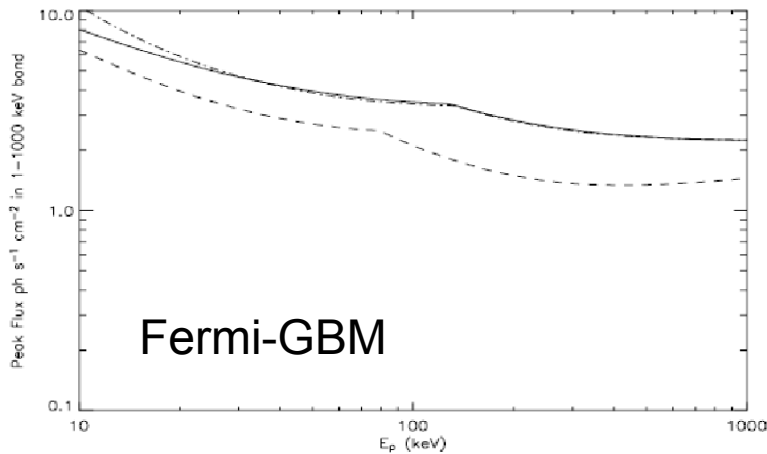

The correlation allows to use long GRBs like **cosmological probes**. In this way we can estimate the cosmological parameters and we can compare these measures with the other ones estimated using different methods.

We must to test the **reliability** of the correlation!!

No-redshift data agree with the correlation parameters?

Instrumental thresholds
(Band, 2003)

E_p - E_{iso} distribution resulting by the simulations
