1FGL J1018.6-5856 and the Galactic Population of Gamma-ray Binaries

Robin Corbet (UMBC/NASA GSFC), C.C. Cheung (NRC/NRL), M. Kerr (Stanford), on behalf of the Fermi Large Area Telescope Collaboration, M.J. Coe (Southampton), F. Di Mille (AAO/LCO), P.G. Edwards (CSIRO), M.D. Filipovic (UWS), J.L. Payne (UWS), J. Stevens (CSIRO), M.A.P. Torres (CfA)

We present the discovery of a new gamma-ray binary system from the search for periodic modulation in the Fermi LAT light curves of all sources in the first Fermi-LAT catalog. 1FGL J1018.6-5856 was found to have a 16.6 day modulation in its gamma-ray flux that is accompanied by spectral variability. We identify counterparts in the X-ray, radio, and optical wavebands using data from the Swift XRT, ATCA, and telescopes at SAAO and LCO. The X-ray and radio counterparts are highly variable: the X-ray flux appears to be modulated on the orbital period with maximum X-ray flux coinciding with the phase of maximum gamma-ray flux. The optical counterpart has a spectral type of approximately O6V((f)) and shows little variability in a series of Swift UVOT observations. The overall properties of 1FGL J1018.6-5856 indicate that it is a member of the rare gamma-ray binary class of objects, and that it shares several properties with LS 5039. However, there are some differences from LS 5039, including the relative phasing of the gamma-ray flux and spectral modulation and the shape of the X-ray light curve. We conclude that 1FGL J1018.6-5856 is a new gamma-ray binary, and its discovery suggests that Fermi has begun to reveal the predicted population of such objects.

Introduction

Two types of interacting binaries containing compact objects are expected to emit gamma rays: microquasars - accreting black holes or neutron stars with relativistic jets - and rotation-powered pulsars interacting with the wind of a binary companion. Microquasars should typically be powerful X-ray sources, while active, and hence may already be known X-ray binaries as in the case of Cygnus X-3. The existence of pulsars interacting with early spectral type stellar companions is predicted as an initial stage in the formation of high-mass X-ray binaries (HMXBs) containing neutron stars. These interacting pulsars are predicted to be weak X-ray emitters, and may not yet be known, or classified, X-ray sources. Gamma-ray binaries may thus not be as rare as it appears, and many systems may await detection.

Detection of 16.6 day Period

A gamma-ray binary is expected to show orbitally-modulated gamma-ray emission due to changes in viewing angle and, in eccentric orbits, the degree of the binary interaction. Periodic modulation has indeed been seen in LS 5039 (3.9 day period), LS 613 303 (26.5 days), and Cygnus X-3 (4.8 hours) and emission is orbital phase dependent for PSR B1259-63 (3.4 years). A search for periodic modulation of gamma-ray flux from LAT sources may thus yield further gamma-ray binaries, potentially revealing the predicted HMXB precursor population. The first Fermi LAT catalog of gamma-ray sources (“1FGL”) contains 1451 sources, many of which do not have confirmed counterparts at other wavelengths and thus are potentially gamma-ray binaries.

In order to search for modulation we made 0.1 - 200 GeV light curves for all 1FGL sources and calculated power spectra of these. In addition to detecting modulation from known binaries, we found a strong signal near 16.6 days from 1FGL J1018.6-5856.

Hunting for New Binaries

The LAT gamma-ray spectrum of 1FGL J1018.6-5856 and best-fit broken power-law model.

The LAT gamma-ray spectrum of 1FGL J1018.6-5856 in the 0.1 - 10 GeV band as measured with the Fermi LAT. Gamma-ray flux and spectral indices for energies below and above 1 GeV, respectively, using a broken power law model.

The orbital modulation of the flux and spectral indices of 1FGL J1018.6-5856 in the 0.1 - 10 GeV band as measured with the Fermi LAT. Gamma-ray flux and spectral indices for energies below and above 1 GeV, respectively, using a broken power law model.

Summary

- 1FGL J1018.6-5856 is a new gamma-ray binary in a 16.6 day orbit with X-ray, optical, and radio counterparts.
- We don’t definitely know what is driving the gamma-ray emission. 1FGL J1018.6-5856 may contain a rapidly rotating pulsar interacting with the wind of an O star.
- So far, we've only found binary periods in bright sources.
- LAT binary search sensitivity is improving as more data accumulates.
- Evolutionary models predict we should see more binaries in the “iceberg” of LAT sources...
